

NONLINEAR FINITE ELEMENT ANALYSIS OF COLUMNS

by

RAJKIRAN MUPPAVARAPU

Presented to the Faculty of the Graduate School of
The University of Texas at Arlington in Partial Fulfillment
of the Requirements
for the Degree of

MASTER OF SCIENCE IN AEROSPACE ENGINEERING

THE UNIVERSITY OF TEXAS AT ARLINGTON

May 2011

ACKNOWLEDGEMENTS

I would like to first thank Dr. Kent Lawrence for his guidance throughout the project. He has been a big source of inspiration for me. I would also like to thank Dr. B.P. Wang and Dr. S. Nomura for taking the time to serve on my committee.

I would also like to thank my friend Mahesh Kumar Varrey for his help and advice. I would also like to thank my roommates for creating a cordial environment.

I wish to thank my parents, Dr. Raghuram Muppavarapu and Madhavi Muppavarapu, who taught me everything I know and supported me over the years. I would also like to thank my sister and grand parents for their love and support. I dedicate this thesis to my family.

April 14, 2011

ABSTRACT

NONLINEAR FINITE ELEMENT ANALYSIS OF COLUMNS

Rajkiran Muppavarapu, M.S.

The University of Texas at Arlington, 2011

Supervising Professor: Dr. Kent L. Lawrence

In many engineering applications structural components are considered to be beams or columns subjected to a range of external loads such as dead weight, wind, temperature changes etc.

In this work a mathematical model has been developed for a sports lighting tower considering it to be a cantilever beam with large deformation. The concept of non-linear P-Delta analysis is applied to the column. Using this model, a tower analysis tool was developed in MATLAB. Using this tool various design alternatives can be examined to evaluate their suitability to a particular task.

A number of example problems from the available literature were solved in ANSYS. The MATLAB program developed here is referred to as the NLFC program and it gave the same results as these test cases, and this process was used to evaluate the validity of the tower analysis tool.

CHAPTER 1

INTRODUCTION

Among the various numerical methods available, finite element method is very popular and widely used. It is perhaps the most sophisticated tool for solving engineering problems. When the structures have complicated shapes the conventional methods fail to give accurate solutions and also it is quite uneconomical and time consuming. Almost any structure having any shape and made of any material can be analyzed by the finite element method. Such an advantage is not available with other methods.

Finite element analysis has now become an integral part of computer aided engineering (CAE) and is being extensively used in the analysis and design of many complex real life systems. While it started off as an extension of matrix methods of structural analysis it was initially perceived as a tool for structural analysis alone, its applications now range from structures to bio mechanics to electromagnetic field problems. Simple linear static problems as well as highly complex nonlinear transient dynamic problems are effectively solved using the finite element method. The field of finite element analysis has matured and now rests on rigorous mathematical foundation. In preprocessing we build the model by defining geometry, specifying element type, defining material properties, creating mesh, applying loading and boundary conditions. In post processing we can extract results such as displacements, stresses etc., time history relation wherever applicable and graphical representation of the results [1].

1.1 Literature Review

1.1.1 Methods of Analysis

Structural analysis can be divided into two groups, analytical methods and numerical methods. Analytical methods cannot easily be used for complex structures and so numerical methods must be used.

The numerical methods of structural analysis can be divided into two types: (1) numerical solutions of differential equations for displacements and stresses and (2) matrix methods based on discrete element idealization.[2]

In the first type, the equations of elasticity are solved for a given structural configuration by using the finite difference techniques or by direct numerical integration. This method involves mathematical approximation of differential equations.

The second method, matrix methods, is a concept that is used to replace the actual continuous structure by a mathematical model made up of structural elements of finite size with known elastic and inertial properties that can be expressed in matrix form.

In matrix methods, particles are of finite size and shape and are referred to as structural elements. The analysis of the entire structure is done by analyzing the assembly of the structural elements. When the size of these elements is decreased, the deformational behavior of the mathematical model (under some restrictions) converges to that of the continuous structure.

There are two types of matrix methods: (1) the displacement method (stiffness method), where displacements are the unknowns, and (2) the force method (flexibility method), where forces are unknowns. In both these methods the analysis can be considered as a combination of individual unassembled structural elements into an assembled structure in which conditions of equilibrium and compatibility are satisfied.

1.1.2 P-Delta Analysis

Using the geometric stiffness matrix is a method to include the secondary effects in the static and dynamic analysis of all types of structural systems [3]. In civil structural engineering this method is referred to as P-Delta analysis. This type of analysis is based on a more physical approach. For example, in building analysis the lateral movement of a story mass to a deformed position generates second-order overturning moments. This additional overturning moments on the building are equal to the sum of the story weights 'P' times the lateral displacements 'Delta'.

For structures where the weight is constant during lateral motions, the P-Delta problem can be linearized. The solution is also obtained directly and exactly without iteration. This method does not require iteration since the total axial force that is applied at each story level is equal to the weight of the building above that level and it remains constant even when lateral loads are applied.

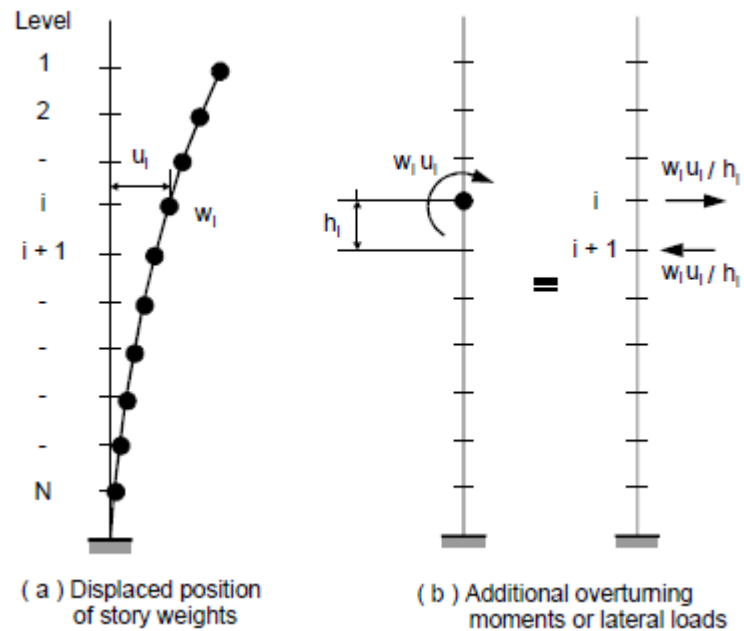

Figure 1.1 Overturning Loads Due to Translation of Story Weights[8]

The vertical cantilever type structure shown in the Figure 1.1 best illustrates the basic problem.

1.1.3 Stiffness matrix for 2D tapered beams

1.1.3.1 Two-dimensional Arbitrarily Oriented Beam Element Elastic Stiffness Matrix

The stiffness matrix for an arbitrarily oriented beam element, as shown in Figure 1.2, is in a manner similar to that used for the bar element. The local axes \bar{x} and \bar{y} are located along the beam element and transverse to the beam element, respectively, and the global axes x and y are located to be convenient for the total structure.[4]

Figure 1.2 Arbitrarily Oriented Beam Element[4]

For a beam element the transformation matrix is defined as:

$$T = \begin{bmatrix} -S & C & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -S & C & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.1)$$

The axial effects are not included yet. Here, $C = \cos\theta$ and $S = \sin\theta$.

The global stiffness matrix for a beam element that includes shear and bending resistance is as follows:

$$\underline{k} = \frac{EI}{L^3} \begin{bmatrix} 12S^2 & -12SC & -6LS & -12S^2 & 12SC & -6LS \\ & 12C^2 & 6LC & 12SC & -12C^2 & 6LC \\ & & 4L^2 & 6LS & -6LC & 2L^2 \\ & & & 12S^2 & -12SC & 6LS \\ & & & & 12C^2 & -6LC \\ \text{Symmetry} & & & & & 4L^2 \end{bmatrix} \quad (1.2)$$

where

'E' is Young's modulus,

'I' is principal moment of inertia about the z axis,

'L' length of the element,

Now, including the axial effects in the element with the shear and principal bending moment effects, the transformation matrix is expanded to:

$$T = \begin{bmatrix} C & S & 0 & 0 & 0 & 0 \\ -S & C & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & C & S & 0 \\ 0 & 0 & 0 & -S & C & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.3)$$

The analysis of a rigid plane frame can be done by using the stiffness matrix equation. A rigid plane frame is defined as a series of beam elements rigidly connected to each other; that is, the original angles made between elements at their joints remain unchanged after deformation. Furthermore, moments are transmitted from one element to another at the joints. Hence, moment continuity exists at the rigid joints. In addition, the element centroids, as well as the applied loads, lie in a common plane.

$$k = \frac{E}{L} \times \begin{bmatrix} AC^2 + \frac{12I}{L^2}S^2 & \left(A - \frac{12I}{L^2}\right)CS & -\frac{6I}{L}S & -\left(AC^2 + \frac{12I}{L^2}S^2\right) & -\left(A - \frac{12I}{L^2}\right)CS & -\frac{6I}{L}S \\ & AS^2 + \frac{12I}{L^2}C^2 & \frac{6I}{L}C & -\left(A - \frac{12I}{L^2}\right)CS & -\left(AS^2 + \frac{12I}{L^2}C^2\right) & \frac{6I}{L}C \\ & & 4I & \frac{6I}{L}S & -\frac{6I}{L}C & 2I \\ & & & AC^2 + \frac{12I}{L^2}S^2 & \left(A - \frac{12I}{L^2}\right)CS & \frac{6I}{L}S \\ & & & & AS^2 + \frac{12I}{L^2}C^2 & -\frac{6I}{L}C \\ \text{Symmetry} & & & & & 4I \end{bmatrix} \quad (1.4)$$

where

'E' is Young's modulus,

'I' is principal moment of inertia about the z axis,

'A' cross-sectional area of the element,

'L' length of the element,

'θ' angle of orientation of element w.r.to global coordinate axes.

Now to apply the above method of constructing stiffness matrix for a tapered beam element; the element is broken down into smaller sections. The section properties for each of these elements are taken from the point on the true tapered beam that corresponds to the midpoint of a given piece.[5]

Figure 1.3 Linear tapered I-beam broken up into 4 smaller uniform segments[5]

Using this procedure the tip deflection results are compared to various cases with number of segments 'n'. The table 1.1 shows the convergence as the number of segments increases.

Table 1.1 Tip displacement error for number of segments used to approximate tapered cantilever[5]

Segments, n	δ (in)	% Error = $\left(\frac{\delta - \delta_t}{\delta_t}\right) 100\%$
1	-3.8692	53.36
2	-2.9349	16.33
3	-2.7104	7.43

6	-2.5690	1.82
10	-2.5392	0.64
20	-2.5269	0.15
50	-2.5235	0.02

1.1.3.2 Geometrical Stiffness Matrix

The elastic stiffness matrix is calculated as shown in the previous section. When large deflections are present, the equations of force equilibrium must be formulated for the deformed configuration of the structure. This means that the linear relationship 'F=KD' between the applied forces 'F' and the displacements 'D' cannot be used. However, because of the presence of large deflections, strain-displacement equations contain nonlinear terms, which must be included in calculating the stiffness matrix.[3]

$$K = K_E + K_G \quad (1.5)$$

The geometric stiffness matrix is given by:

$$K_G = F_{axial}/L \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 6/5 & L/10 & 0 & -6/5 & L/10 \\ 0 & L/10 & 2L^2/15 & 0 & -L/10 & L^2/30 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -6/5 & -L/10 & 0 & 6/5 & -L/10 \\ 0 & L/10 & L^2/30 & 0 & -L/10 & 2L^2/15 \end{bmatrix} \quad (1.6)$$

where

'F_{axial}' is the axial nodal force,

'L' is length of the element.

1.1.4 Second moment of area for any cross section defined as polygon

The second moment of area of a polygon can be calculated by adding up the individual contributions of each segment of the polygon[6].

Figure 1.4 Cross Section of the Sports Lighting Tower

For this problem, each segment is a triangle. The number of triangles is equal to the number of sides of the polygon. Two corners of each triangle segment are on the perimeter of the polygon and the third corner is the origin of the polygon. The following are the equations to calculate the second moments of area of the polygon:

$$I_x = \frac{1}{12} \sum_{i=1}^n (y_i^2 + y_i y_{i+1} + y_{i+1}^2) a_i$$

$$I_y = \frac{1}{12} \sum_{i=1}^n (x_i^2 + x_i x_{i+1} + x_{i+1}^2) a_i \quad (1.7)$$

$$I_{xy} = \frac{1}{24} \sum_{i=1}^n (x_i y_{i+1} + 2 x_i y_i + 2 x_{i+1} y_{i+1} + x_{i+1} y_i) a_i$$

- $a_i = x_i y_{i+1} - x_{i+1} y_i$ is twice the area of the elementary triangle,
- index 'i' passes overall 'n' points in the polygon, which is considered closed, i.e. point 'n+1' is point 1.

According to these formulae the points defining the polygon are in anticlockwise order.

For a clockwise defined polygon these formulae will give negative values.

1.1.5 Volume of frustum

The portion of a solid that lies between two parallel planes that are cutting it is called a frustum.

Figure 1.5 Examples: Pentagonal and square frusta

The volume of a pyramidal frustum where the bases are n-sided polygons is:

$$V = \frac{nh}{12} (a_1^2 + a_2^2 + a_1 a_2) \cot \frac{180}{n} \quad (1.8)$$

where

' a_1 ' and ' a_2 ' are the sides of the bottom and top of the frustum respectively,

' h ' is the height of the frustum.

1.2 Project Motivation

Light steel structures have been extensively used as being the most effective in practical application. The main advantages of this kind of structures are the effective use of materials and quick erection as well as their good characteristics. Over the past two decades, solution of the buildings with tapered frames, manufactured from high tensile strength steel, have become a standard. Their contours are quite close to the bending moment diagram, so the cross-section is effectively utilized. Analysis of such kind of frames is rather complicated and not widely investigated. This concept can be applied to a range of structures in various fields.[10]

The results of buckling analysis for a tapered column under the combination of an axial force and a bending moment cannot be obtained just by adding the solutions obtained for those loads acting separately because this dependency is non-linear.

A FEM stability analysis of tapered beam columns by Sapalas, Samofalov and Saraskinas was done in 2004.[10] In this a theoretical and a numerical analysis of tapered beam columns subjected to a bending moment and an axial force was conducted. Critical forces were calculated by using a correction factor.

The analysis of tapered members are covered in many textbooks on structural analysis, e.g., Przemieniecki.[2] The analysis involves lengthy calculations for each member. The alternative is to use methods such as finite element method, where the member is represented by a number of segments and the stiffness matrix for the segments are superimposed to produce the stiffness matrix for the whole member. Because of current digital computer capacities the increase in the number of equations due to the process of member discretization is not disadvantageous. The disadvantage is the huge amount of input data required, especially in the case of large structures.

1.3 Project Objectives

There are three main objectives in this project:

- To reduce the amount of input data required to analyze large structures.
- To reduce the number of steps in analyzing the structure.
- To develop a robust tool in MATLAB to analyze a large structure, by using the methods mentioned above.

A sports lighting tower as shown in Figure 1.6, will be analyzed to find the deformations and stresses under wind loading and self weight. The tower has polygonal cross section.

Figure 1.6 A Sports Lighting Tower[11]

The thesis will have the following sections:

- Chapter 2: NLFC Program Setup and Verification
- Chapter 3: Discussion of Results
- Chapter 4: Conclusion and Future Work

CHAPTER 2
NLFC PROGRAM SETUP AND VERIFICATION

2.1 NLFC Program Setup

The first step in the program is to input the number of sides of the regular polygon. The position of the nodes is decided upon and divided into the number of segments as required. From the position of nodes, a loop is written to calculate the length of each element. Using the length of each element, the taper ratio and the thickness of each element; the radius of the circumcircle and incircle of the n-polygon at each node is calculated.

2.1.1 Geometry

Each element is in the shape of a frustum. Now, using the radius of the circumcircle and incircle at each node, the length of each side of the polygon is found using the following formula:

$$S = \text{Radius} \times \sin(\pi/n) \quad (2.1)$$

where

'n' is the number of sides of the polygon.

The volume of each element in the shape of a frustum is calculated using the following formula, as mentioned in chapter 1.

$$V = \frac{nh}{12} (S_1^2 + S_2^2 + S_1 S_2) \cot \frac{180}{n} \quad (2.2)$$

Using the volume of each element the weight of each element is calculated by using the formula:

$$\text{Weight} = \text{Volume} \times \text{Density} \quad (2.3)$$

The self weight of each element is a part of the axial load. The axial load at each node is equal to the sum of the axial load at all the nodes above that particular node. The axial load at

the nodes due to structural parts such as light fixtures etc., of the actual structure is also added to this.

Next the second moment of area at each node with respect to different axes is calculated according to section 1.1.4 of Chapter 1. For this, the coordinates of the polygon at each node are to be calculated. This is done generating a polygon in MATLAB by using the radius of the circumcircle and limiting the number of points to the number of sides of the polygon. The following command is used to generate the circle:

$$t = \text{linspace}(0, 2 * \pi, n + 1) \quad (2.4)$$

Then each coordinate is calculated using the angle at which each point was used to make the circle, using the following formula:

$$\begin{aligned} X &= \text{Radius} \times \sin(t) \\ Y &= \text{Radius} \times \cosine(t) \end{aligned} \quad (2.5)$$

A total of 'n+1' sets of coordinates are generated but the first set of coordinates is the same as the 'n+1'th set.

2.1.2 Wind Loading

The effect of wind forces on the structure is calculated. The wind forces are lateral loads on the structure. The calculation of wind loads is done as per ASCE 7-02 code for cantilevered structures classified as other structures.

There are various constants that need to be calculated to get the wind forces acting on each element. The first is 'K_z', velocity pressure exposure coefficient at height 'z'. the formula to calculate 'K_z' is as follows:

$$\begin{aligned} \text{If } Z < 15 \text{ then: } K_z &= 2.01 * (15/Z_g)^{(2/\alpha)} \\ \text{If } Z \geq 15 \text{ then: } K_z &= 2.01 * (Z/Z_g)^{(2/\alpha)} \end{aligned} \quad (2.6)$$

where 'Z' is the height of the element above the ground.

'Z_g' and 'α' are called terrain exposure coefficients. These values can be obtained in Table 2.1.

Table 2.1 Terrain Exposure Constants

Exposure Category	α	Z_g (ft)
B	7.0	1200
C	9.5	900
D	11.5	700

The next constant is ' K_{zt} ', the topographic factor. For the problem here the topographic factor is '1' i.e. the topographic factor does not play a role in the wind forces. The third constant is ' K_d ', the wind directionality factor. The value of the constant can be determined from the table below.

Table 2.2 Wind Directionality Factor, K_d

Structure Type	K_d
Square	0.90
Hexagon	0.95
Round	0.95

The velocity of the wind in miles per hour is ' V '. The next constant is ' q_z '. The formula is as follows:

$$q_z = 0.00256 \times K_z \times K_{zt} \times K_d \times V^2 \times I \quad (2.7)$$

The net design wind forces are obtained from the following formula:

$$F = q_z \times G \times C_f \times D \text{ (lb/ft)} \quad (2.8)$$

where

'G' is the gust factor. The gust factor the structure is given as 1.14.

' C_f ' is drag coefficient and is obtained from the following table.

Table 2.3 Force Coefficients, C_f

Cross-section	Type of Surface	C_f for h/D values of		
		1	7	25
Square	All	1.3	1.4	2.0
Square	All	1.0	1.1	1.5
Hexagonal or Octagonal	All	1.0	1.2	1.4
Round	Moderately smooth	0.5	0.6	0.7

Using all the above equations and constants the magnitude of the wind load on each element is calculated. This uniform distributed load on each element is converted into nodal lateral forces and moments.

Figure 2.1 (a) Cantilever Beam Subjected to a Uniformly Distributed Load and (b) The Equivalent Nodal Force System[4]

At all nodes the following sign conventions are used:

1. Moments are positive in the counterclockwise direction.
2. Rotations are positive in the counterclockwise direction.
3. Forces are positive in the positive y direction.
4. Displacements are positive in the positive y direction.

The formulae to calculate the value of these nodal loads resulting from a uniformly distributed load on the beam element are as follows:

$$\begin{aligned}
 F &= w L / 2 \\
 M &= w L^2 / 12
 \end{aligned}
 \tag{2.9}$$

where

'w' is the uniformly distributed load

'L' is the length of the beam element.

2.1.3 Global Stiffness Matrix

The next step is to calculate the stiffness matrix for each element using the procedure mentioned in section 1.1.3 of Chapter 1. The global stiffness matrix for the entire structure is then assembled from all the individual element stiffness matrices.

The force matrix is assembled from the nodal forces calculated in each direction. The first three rows and first three columns of the global matrix are eliminated as they represent the first node for which all degrees of freedom are constrained. The nodal deformations are calculated from the following formula:

$$D = \text{inv} (Kg) \times F_{\text{mat}} \quad (2.10)$$

where

'D' is the nodal deformation matrix,

'Kg' is the modified global matrix

"F_{mat}" is the force matrix.

The resulting deformation matrix represents the deformation in global coordinates. Using this matrix the deformations for each node along with the stiffness matrix for each individual element are used to back calculate the nodal forces such as bending moment etc., in the local system.[7]

For large deformations of the body, the stress in the cross-section is calculated using an extended version of Euler-Bernoulli beam bending theory formula. First the following assumptions must be made:

1. Assumption of plane sections - before and after deformation the considered section of body remains flat (i.e. is not distorted).
2. Shear and normal stresses in this section that are perpendicular to the normal vector of cross section have no influence on normal stresses that are parallel to this section.

Large bending considerations should be implemented when the bending radius ρ is smaller than ten section heights h :

$$\rho < 10h$$

With those assumptions the stress in large bending is calculated as:

$$\sigma = \frac{F_{axial}}{A} + \frac{M}{\rho A} + \frac{M}{I_x'} y \frac{\rho}{\rho + y} \quad (2.11)$$

where

' F_{axial} ' is the normal force

' A ' is the section area

' M ' is the bending moment

' ρ ' is the local bending radius (the radius of bending at the current section)

I_x' is the area moment of inertia along the x axis, at the y place

' y ' is the position along y axis on the section area in which the stress σ is calculated

When bending radius ρ approaches infinity and y is near zero, the original formula is back:

$$\sigma = \frac{F_{axial}}{A} \pm \frac{My}{I} \quad (2.12)$$

As a result of rotation of the element there will be a contraction of the element. These deformations are called fictitious deformations, when applied together with linear analysis will give the correct results for large deflections.

Figure 2.2 Fictitious Deformations v_ϕ on a bar element[3]

The formula to calculate fictitious deformation is:

$$v_{\phi} = \frac{-1}{2l} (u_4 - u_2)^2 \quad (2.13)$$

2.2 NLFC Program Verification

A series of simple example problems based on a cantilever beam were created. The solutions were obtained by theoretical calculations. The problems were solved using the NLFC program. The example problems were also solved using ANSYS. The results obtained from the program and ANSYS were compared to the results from theoretical calculations. The different example problems are as follows:

1. Cantilever beam (single element) subjected to a point load at the free end.
2. Cantilever beam divided into 2 elements subjected to a point load at the free end.
3. Cantilever beam (single element) subjected to uniformly distributed load.
4. Cantilever beam divided into 2 elements subjected to uniformly distributed load.
5. Cantilever beam divided into 3 elements subjected to uniformly distributed load and self weight.
6. ANSYS – VM 34 – Bending of a Tapered Plate (Beam)

CHAPTER 3

RESULTS

3.1 Verification Problems

For the verification problems 3.1.1, 3.1.2, 3.1.3, 3.1.4 and 3.1.5 all the data was chosen arbitrarily.

3.1.1 Cantilever beam (single element) subjected to a point load at the free end

Assumptions: 1 element, Length = 360 in, $P = 1000$ lb, $I = 100$ in⁴, $E = 3 \times 10^7$ psi

Figure 3.1 Cantilever Beam – Concentrated Load P at the Free End

Theoretical Calculations:

- $\delta_{\max} = PL^3/3EI$

$$\delta_{\max} = \frac{-1000 \times 360^3}{3 \times 3 \times 10^7 \times 100} = -5.1840 \text{ in.}$$

- $\theta = PL^2/2EI$

$$\theta = \frac{-1000 \times 360^2}{2 \times 3 \times 10^7 \times 100} = -0.0216 \text{ rad.}$$

Table 3.1 Comparison of Results for Problem 3.1.1

	δ_{\max} (in)	θ (rad)	% error δ_{\max}	% error θ
From Theory	-5.1840	-0.0216	NA	NA
ANSYS	-5.1840	-0.0216	0.0	0.0
NLFC	-5.1840	-0.0216	0.0	0.0

The maximum deformation and slope values obtained from ANSYS and NLFC match with the values obtained from theoretical calculations.

3.1.2 Cantilever beam divided into 2 elements subjected to a point load at the free end

Assumptions: 2 elements, Length = 360 in, P = 1000 lb, I = 100 in⁴, E = 3x10⁷ psi

Figure 3.2 Cantilever Beam – Concentrated Load P at the Free End (2 elements)

Theoretical Calculations:

- $\delta_{\max} = PL^3/3EI$

$$\delta_{\max} = \frac{-1000 \times 360^3}{3 \times 3 \times 10^7 \times 100} = -5.1840 \text{ in.}$$

- $\theta = PL^2/2EI$

$$\theta = \frac{-1000 \times 360^2}{2 \times 3 \times 10^7 \times 100} = -0.0216 \text{ rad.}$$

- $\delta_{\text{mid length}} = PX^2 \times (3L-X) / 6EI$

$$\delta_{\text{mid length}} = \frac{-1000 \times 180^2 \times (3 \times 360 - 180)}{6 \times 3 \times 10^7 \times 100} = -1.62 \text{ in.}$$

- $\theta_{\text{mid length}} = PX \times (2L-X) / 2EI$

$$\theta_{\text{mid length}} = \frac{-1000 \times 180 \times (2 \times 360 - 180)}{2 \times 3 \times 10^7 \times 100} = -0.0162 \text{ rad.}$$

Table 3.2 Comparison of Results for Problem 3.1.2

	$\delta_{\text{mid length}}$ (in)	$\theta_{\text{mid length}}$ (rad)	δ_{max} (in)	θ (rad)	% error δ_{max}	% error θ
From Theory	-1.62	-0.0162	-5.1840	-0.0216	NA	NA
ANSYS	-1.62	-0.0162	-5.1840	-0.0216	0.0	0.0
NLFC	-1.62	-0.0162	-5.1840	-0.0216	0.0	0.0

The percentage error in the deformation and slope values obtained from ANSYS and NLFC when compared with the values from theoretical calculation is 0.0%.

3.1.3 Cantilever beam (single element) subjected to uniformly distributed load

Assumptions: 1 element, Length = 360 in, $W = 1 \text{ lb/in}$, $I = 100 \text{ in}^4$, $E = 3 \times 10^7 \text{ psi}$

Figure 3.3 Cantilever Beam – Uniformly distributed load w

Theoretical Calculations:

- $\delta_{\text{max}} = WL^4 / 8EI$

$$\delta_{\text{max}} = \frac{-1 \times 360^4}{8 \times 3 \times 10^7 \times 100} = -0.6998 \text{ in.}$$

- $\theta = PL^3 / 6EI$

$$\theta = \frac{-1 \times 360^3}{6 \times 3 \times 10^7 \times 100} = -0.0026 \text{ rad.}$$

Table 3.3 Comparison of Results for Problem 3.1.3

	$\bar{\delta}_{\max}$ (in)	θ (rad)	% error $\bar{\delta}_{\max}$	% error θ
From Theory	-0.6998	-0.0026	NA	NA
ANSYS	-0.6998	-0.0026	0.0	0.0
NLFC	-0.6998	-0.0026	0.0	0.0

The maximum deformation and slope values obtained from ANSYS and NLFC match with the values obtained from theoretical calculations.

3.1.4 Cantilever beam divided into 2 elements subjected to uniformly distributed load

Assumptions: 2 elements, Length = 360 in, $W = 1$ lb/in, $I = 100$ in⁴, $E = 3 \times 10^7$ psi

Figure 3.4 Cantilever Beam – Uniformly distributed load ω (2 elements)

Theoretical Calculations:

- $\bar{\delta}_{\max} = WL^4 / 8EI$

$$\bar{\delta}_{\max} = \frac{-1 \times 360^4}{8 \times 3 \times 10^7 \times 100} = -0.6998 \text{ in.}$$

- $\theta = PL^3 / 6EI$

$$\theta = \frac{-1 \times 360^3}{6 \times 3 \times 10^7 \times 100} = -0.0026 \text{ rad.}$$

- $\bar{\delta}_{\text{mid length}} = WX^2 \times (6L^2 - 4LX + X^2) / 24EI$

$$\bar{\delta}_{\text{mid length}} = \frac{-1 \times 180^2 \times (6 \times 360^2 - 4 \times 360 \times 180 + 180^2)}{24 \times 3 \times 10^7 \times 100} = -0.2479 \text{ in.}$$

- $\theta_{\text{mid length}} = WX \times (3L^2 - 3LX + X^2) / 6EI$

$$\theta_{\text{mid length}} = \frac{-1 \times 180 \times (3 \times 360^2 - 3 \times 360 \times 180 + 180^2)}{6 \times 3 \times 10^7 \times 100} = -0.0023 \text{ rad.}$$

Table 3.4 Comparison of Results for Problem 3.1.4

	$\delta_{\text{mid length}}$ (in)	$\theta_{\text{mid length}}$ (rad)	δ_{max} (in)	θ (rad)	% error δ_{max}	% error θ
From Theory	-0.2479	-0.0023	-0.6998	-0.0026	NA	NA
ANSYS	-0.2479	-0.0023	-0.6998	-0.0026	0.0	0.0
NLFC	-0.2479	-0.0023	-0.6998	-0.0026	0.0	0.0

The percentage error in the deformation and slope values obtained from ANSYS and NLFC when compared with the values from theoretical calculation is 0.0%.

3.1.5 Cantilever beam divided into 3 elements subjected to uniformly distributed load and self weight as axial load

Assumptions: 3 elements, $L = 180$ in, $W = 1$ lb/in, $I = 100$ in⁴, $E = 3 \times 10^7$ psi

Figure 3.5 Cantilever Beam – Uniformly distributed load ω and Self Weight as the Axial Load at each node

Both linear and non-linear analysis was carried out in ANSYS and the NLFC program.

Table 3.5 Comparison of Results for Problem 3.1.5

	ANSYS (linear)	NLFC (linear)	ANSYS (non-linear)	NLFC (non-linear)

3.1.6 ANSYS – VM 34 – Bending of a Tapered Plate (Beam)

A tapered cantilever plate of rectangular cross-section is subjected to a load F at its tip.

Find the maximum deflection $\bar{\delta}$ and the maximum principal stress σ_1 in the plate.

Assumptions: $E = 30 \times 10^6$ psi, $\nu = 0.0$, $L = 20$ in, $d = 3$ in, $t = 0.5$ in, $F = 10$ lbs

(a)

(b)

Figure 3.6 Tapered Cantilever Beam Element. (a) Problem Sketch , (b) Finite element Model Beam 44[12]

For the beam elements, the area and Y dimension of the beam are not used and are input as 1.0. Node 12 is arbitrarily located at $Z = 1.0$ in order to define the orientation of the beam. The problem is also solved using tapered sections beam elements (BEAM188).

Table 3.6 Comparison of Results for Problem 3.1.6

	Theory	ANSYS BEAM 44	ANSYS BEAM 188	NLFC Program
Max. End Deflection (in)	-0.042667	-0.043109	-0.042792	-0.042667
Stress Max. (psi)	1600.00	1600.00	1599.966	1600.00

- The percentage error in maximum end deflection by using BEAM 44 element in ANSYS is 1.04%.
- The percentage error in maximum principle stress by using BEAM 44 element in ANSYS is 0.0%.
- The percentage error in maximum end deflection by using BEAM 188 element in ANSYS is 0.29%.
- The percentage error in maximum principle stress by using BEAM 188 element in ANSYS is 0.002%.
- The percentage error in maximum end deflection by using the NLFC program is 0.0%.
- The percentage error in maximum principle stress by using the NLFC program is 0.0%.

3.1.7 ANSYS – VM 5 – Laterally Loaded Tapered Support Structure

A cantilever beam of thickness t and length ℓ has a depth which tapers uniformly from d at the tip to $3d$ at the wall. It is loaded by a force F at the tip, as shown. Find the maximum bending stress at the mid-length ($X = \ell/2$) and the fixed end of the beam.

Figure 3.7 Cantilever Beam Problem Sketch[12]

Two different solutions are obtained. The first solution uses lower order PLANE 42 elements and the second solution uses higher order PLANE 82 elements. The 2 inch thickness is incorporated by using the plane stress with thickness option. Poisson's ratio is set to 0.0 to agree with beam theory.

Table 3.7 Comparison of Results for Problem 3.1.7

	Theory	ANSYS PLANE 42	ANSYS PLANE 82	NLFC Program
Stress at mid-length (psi)	8333	8163.656	8363.709	8333.333
Stress at fixed end (psi)	7407	7151.096	7408.980	7407.407

- The percentage error in stress at mid length by using PLANE 42 element in ANSYS is 2.03%.
- The percentage error in stress at fixed end by using PLANE 42 element in ANSYS is 3.46%.
- The percentage error in stress at mid length by using PLANE 82 element in ANSYS is 0.37%.
- The percentage error in stress at fixed end by using PLANE 42 element in ANSYS is 0.03%.
- The percentage error in stress at mid length by using the NLFC program is 0.004%.
- The percentage error in stress at fixed end by using the NLFC program is 0.006%.

3.1.8 ANSYS – VM 136 – Large Deflection of a Bar

A slender bar of cross-sectional height h , and area A , fixed at the base and free at the upper end, is loaded with a buckling load F . Determine the displacement (ΔX , ΔY , Θ) of the free end.

$E = 30 \times 10^6$ psi, $l = 100$ in, $A = 0.25$ in², $h = 0.5$ in, $F = 39.13$ lb.

Figure 3.8 Buckled Bar Problem Sketch[12]

Table 3.8 Comparison of Results for Problem 3.1.8

	ANSYS BEAM 3	NLFC Program
Max. End Deflection y- direction (in)	-0.5217×10^{-3}	-0.5218×10^{-3}
Max. End Deflection x- direction (in)	0	0
Slope (rad)	0	0

- The percentage error in end deflection in y-direction by using the NLFC program is 0.019% when compared to ANSYS.
- The percentage error in end deflection in x-direction by using the NLFC program is 0.0% when compared to ANSYS.
- The percentage error in slope at the free end by using the NLFC program is 0.0% when compared to ANSYS.

3.2 Nonlinear Analysis of a Sports Lighting Tower

The non-linear column problem chosen here is that of a sports lighting tower. The design data was provided by Keystone Industries, LP.[11]

The design data is as follows:

Pole height: 120 ft

Pole bottom diameter: 30.00 in

Taper: 0.140 in/ft

Column shape: 18 sided polygon

The whole column is divided into 3 shafts in the following manner:

Table 3.9 Shaft Design Data

Section No.	OD. Top (in)	OD. Bottom (in)	Thickness (in)	Design- Length (ft)	Overlap (ft)
1	14.075	20.500	0.188	45.893	-
2	19.664	24.500	0.250	34.542	3.2917
3	23.475	30.000	0.313	46.607	3.7500

Material properties:

Young's modulus: 2.900E7 psi,

Yield stress: 65000.00 psi

Poisson ratio: 0.3

Weight: 490 lb/ft³

Load case factors:

Gust factor for structure: 1.14

Important factor: 1.00

Drag coefficient: 0.58

Direction of structure weight: X

Wind velocity in x-direction: 0.00 mph

Wind velocity in y-direction: 90.00 mph

Wind velocity in z-direction: 0.00 mph

There are other applied concentrated loads because of the light structures that are applied at different nodes.

3.2.1 Non-linear analysis of Tower in ANSYS and NLFC

A Beam 3 element is used in ANSYS. The same problem is solved using the NLFC code developed. These results are compared with the data provided by Keystone Industries, LP.

- The data given seems to have left out the nodal deformation resulting from nonlinear analysis.
- The percentage error will be compared here taking ANSYS values as reference.

- The percentage error in deformation in x-direction at the free end by using the NLFC program is 2.74%.

- 1 The maximum axial stress is 2.8196 ksi and occurs in element 11 by using ANSYS.
- 2 The maximum axial stress is 2.8157 ksi and occurs in element 11 by using the NLFC program.

CHAPTER 4

CONCLUSION AND FUTURE WORK

4.1 Advantages of the NLFC Program

The NLFC program is a very robust tool. This can be determined from the results and comparisons shown in Chapter 3. The process of analyzing a column or beam like structure from start to finish is faster than ANSYS, as all the calculations such as loads, moments etc. are done within the program. The program can be easily modified to work with any kind of structure such as an aeroplane wing, just by generating an aerofoil design instead of a regular polygon as in the program.

4.2 Limitations of the NLFC Program

The NLFC program can be used for regular polygons only. The program uses the concept of tapered beams by approximating the properties of each element to the properties of the element at the geometrical centre. The program needs to be modified to analyze 3D structures.

4.3 Discussion of Results of the Sports Lighting Tower

The NLFC program shows excellent agreement in deformation in y-direction, slope and bending stresses with the data provided by Keystone Industries, LP. The most serious disagreement with the given data comes in from deformation in x-direction results from ANSYS. For nodal deformations in x-direction the data given seems to have left out the nodal deformation resulting from nonlinear analysis.

4.4 Future Work

The results show that there are certain advantages to using the NLFC program. However, these advantages can be increased and the errors reduced by implementing a 3

dimensional approach and also calculating the element properties along the length. The ability to generate and analyse irregular polygons can also be considered.
